

Hamro Hospital

VS Code Run Guide

This guide explains the easiest way to run the completed Hamro Hospital Management System from VS Code or by double-clicking the startup script.

1. First-time setup on Windows

Open the project folder in VS Code, then use one of these methods.

Option A: Double-click run.bat in the project root.

Option B: In VS Code Terminal, run:

```
run.bat
```

The script automatically creates .venv, installs requirements, runs migrations, creates demo accounts, and starts the server.

2. Linux/macOS

```
chmod +x run.sh ./run.sh
```

3. Daily use after setup

After the first setup, VS Code may automatically activate the virtual environment. Then you can run:

```
cd hamro_hospital python manage.py runserver
```

You do not need to create passwords again every day. Demo passwords remain the same unless you delete the database or manually change them.

4. Login details for testing

Username	Password / Purpose
admin	password - Super Admin
registration	password - Registration Counter
cashier	password - Cash Counter
doctor	password - Doctor
laboratory	password - Laboratory
radiology	password - Radiology
pharmacy	password - Pharmacy
admission	password - Admission
nursing	password - Nursing
accounts	password - Finance / Accounts

5. If the database is deleted

If db.sqlite3 is deleted or you are using a fresh database, you do not need to manually create every password. Rebuild the database and demo accounts with these commands:

```
cd hamro_hospital python manage.py migrate python manage.py create_demo_accounts python manage.py runserver
```

The create_demo_accounts command recreates all demo staff logins and sets their password to:
password

If you use run.bat or run.sh, the script already runs migrations and creates demo accounts for you automatically.

6. URLs

Page	URL
Homepage	http://127.0.0.1:8000/
Staff Login	http://127.0.0.1:8000/accounts/login/
Django Admin	http://127.0.0.1:8000/admin/
System Readiness	http://127.0.0.1:8000/accounts/system-readiness/

7. If something does not run

Check that Python is installed and available in PATH. Then run:

```
python --version pip --version
```

If dependencies are missing, run the startup script again. If migrations are pending, the script will apply them automatically.
